Introduction

The aquatic plant community of a lake is full of complex interactions that contribute to the overall health of an aquatic ecosystem. Every level of the aquatic food chain from bacteria and invertebrates to fish and waterfowl are dependent upon aquatic plants to some degree for their survival (Engel, 1985; Wetzel, 2001). Photosynthesis and respiration are important in maintaining clear waters (Engel, 1990). Aquatic plants stabilize sediments and absorb wave action which in turn prevents turbidity caused by suspended sediments. Light penetration, excess nutrients from run-off, wave action and lake morphometry all affect the plant community of the littoral zone (Barko 1988; Duarte and Kalff, 1986). The importance of aquatic plants in an aquatic ecosystem creates the need to study the diversity, density and distribution of the aquatic plant community as well as an examination of the factors impacting the plant community.

Aquatic Plant Surveys were conducted on Halfmoon Lake during June and August of 2008 through 2014 by water resources staff at the Wisconsin Department of Natural Resources.

Methods

Half Moon Lake is a 135 acre oxbow lake with 5.2 miles of shoreline and a maximum depth of 13.8 feet. Plant surveys were conducted according to the Wisconsin Department of Natural Resources guidelines using the Point–Intercept method that can be found at: <http://www.uwsp.edu/cnr-ap/UWEXLakes/Documents/ecology/Aquatic%20Plants/PI-Protocol-2010.pdf> (Hauxwell et al. 2010). A 36 m sampling grid consisting of 430 points was used in June 2008, August 2008 and June 2009 (Map 1). A 43 m grid consisting of 430 points was used August 2009 thru August 2014 (Map 2). At each Point-Intercept point one sample was collected using a steel thatching rake. The aquatic plant species present on the rake were identified and recorded. Each species was given a density rating based on the total coverage of the plant on the rake (1 – few, 2 – moderate, 3 – abundant). Visual inspections were done between points in order to record the presence of any species that did not occur at the sampling sites. Plant species present were collected and saved for preparation of voucher specimens. Depth was recorded at each sample site. Depths were classified into four zones: zone 1 = 0 – 1.5 ft; zone 2 = 2– 5 ft; zone 3 = 5.5 – 10 ft; zone 4 = 10.5 – 20 ft. Sediment data were collected at each site and classified as muck, sand or rock.

The percent frequency of occurrence of each plant species was calculated (number of sampling sites at which it occurred / total number of sampling sites). Relative frequency was calculated based on the number of occurrences of a species relative to all species' occurrences. A mean rake fullness where present was calculated for each species (sum of a species' rake fullness ratings / number of sampling sites at which it occurred). Relative rake fullness was calculated based on the total rake fullness of each species relative to all species rake fullness rankings. The relative frequency and relative rake fullness were summed to obtain a dominance value for each species.

The Aquatic Macrophyte Community Index (AMCI) was used to define the quality of the aquatic plant community based on seven parameters: the maximum rooting depth, the percentage of the littoral zone vegetated, the relative frequencies of submerged species, sensitive species and exotic species, Simpson's Diversity Index and the total number of taxa. Each parameter was scaled from 1-10 with 10 representing the most desirable condition. The scaled values were then summed to obtain the AMCI (Nichols et al., 2000).

The Floristic Quality Index (FQI) was used to assess each community's resemblance to an undisturbed condition. Coefficients of conservatism are values assigned to plant species based on their ties to a pre-settlement condition. Plants are given a value on a scale of 1 to 10 based on the

probability that a species will occur in a disturbed habitat with higher values given to plants that are less likely to occur in a disturbed habitat (Nichols, 1999). Coefficient of conservatism values are assigned only to native species that would normally be found in a lake environment.

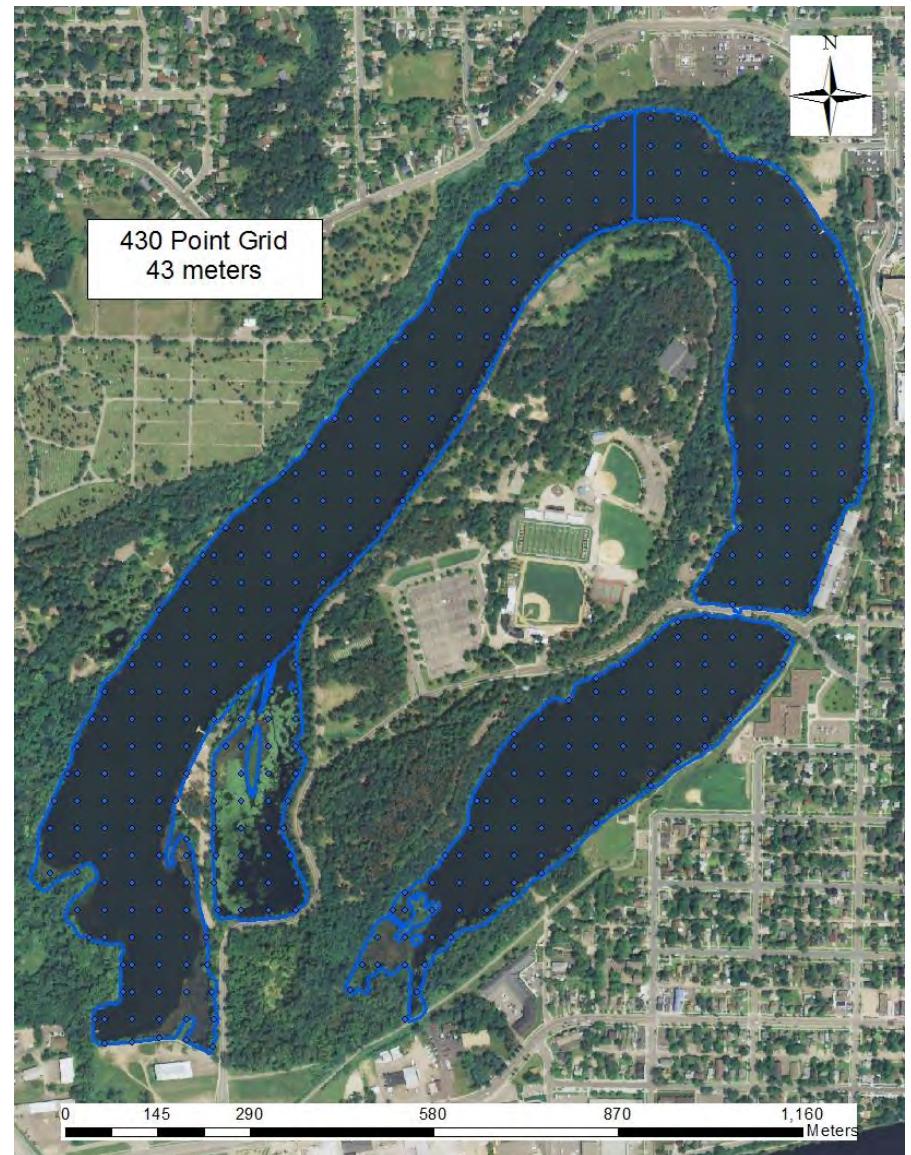

$$FQI = \text{Average Coefficient of conservatism} * \sqrt{\text{Number of species}}$$

The AMCI and FQI of each area were compared to those of all Wisconsin Lakes and Lake in Northern Central Hardwood Forested Region.

Simpson's Diversity Index (SDI) was used to measure the diversity of the plant communities in each survey. The formula measures the probability that two individuals from the same community will be the same species. Values for SDI range from 0-1 where a value of 0 indicates two individuals will always be the same species and a value of 1 indicates two individuals will always be different species.

$$SDI = 1 - (\text{Sum (frequency of occurrence of one species/sum frequency of all species)})$$

Chi-square analysis was used to determine significant differences between survey periods in the frequency of occurrence of each species. Comparisons were made between spring and summer periods within each year and spring vs. spring and summer vs. summer between consecutive years.

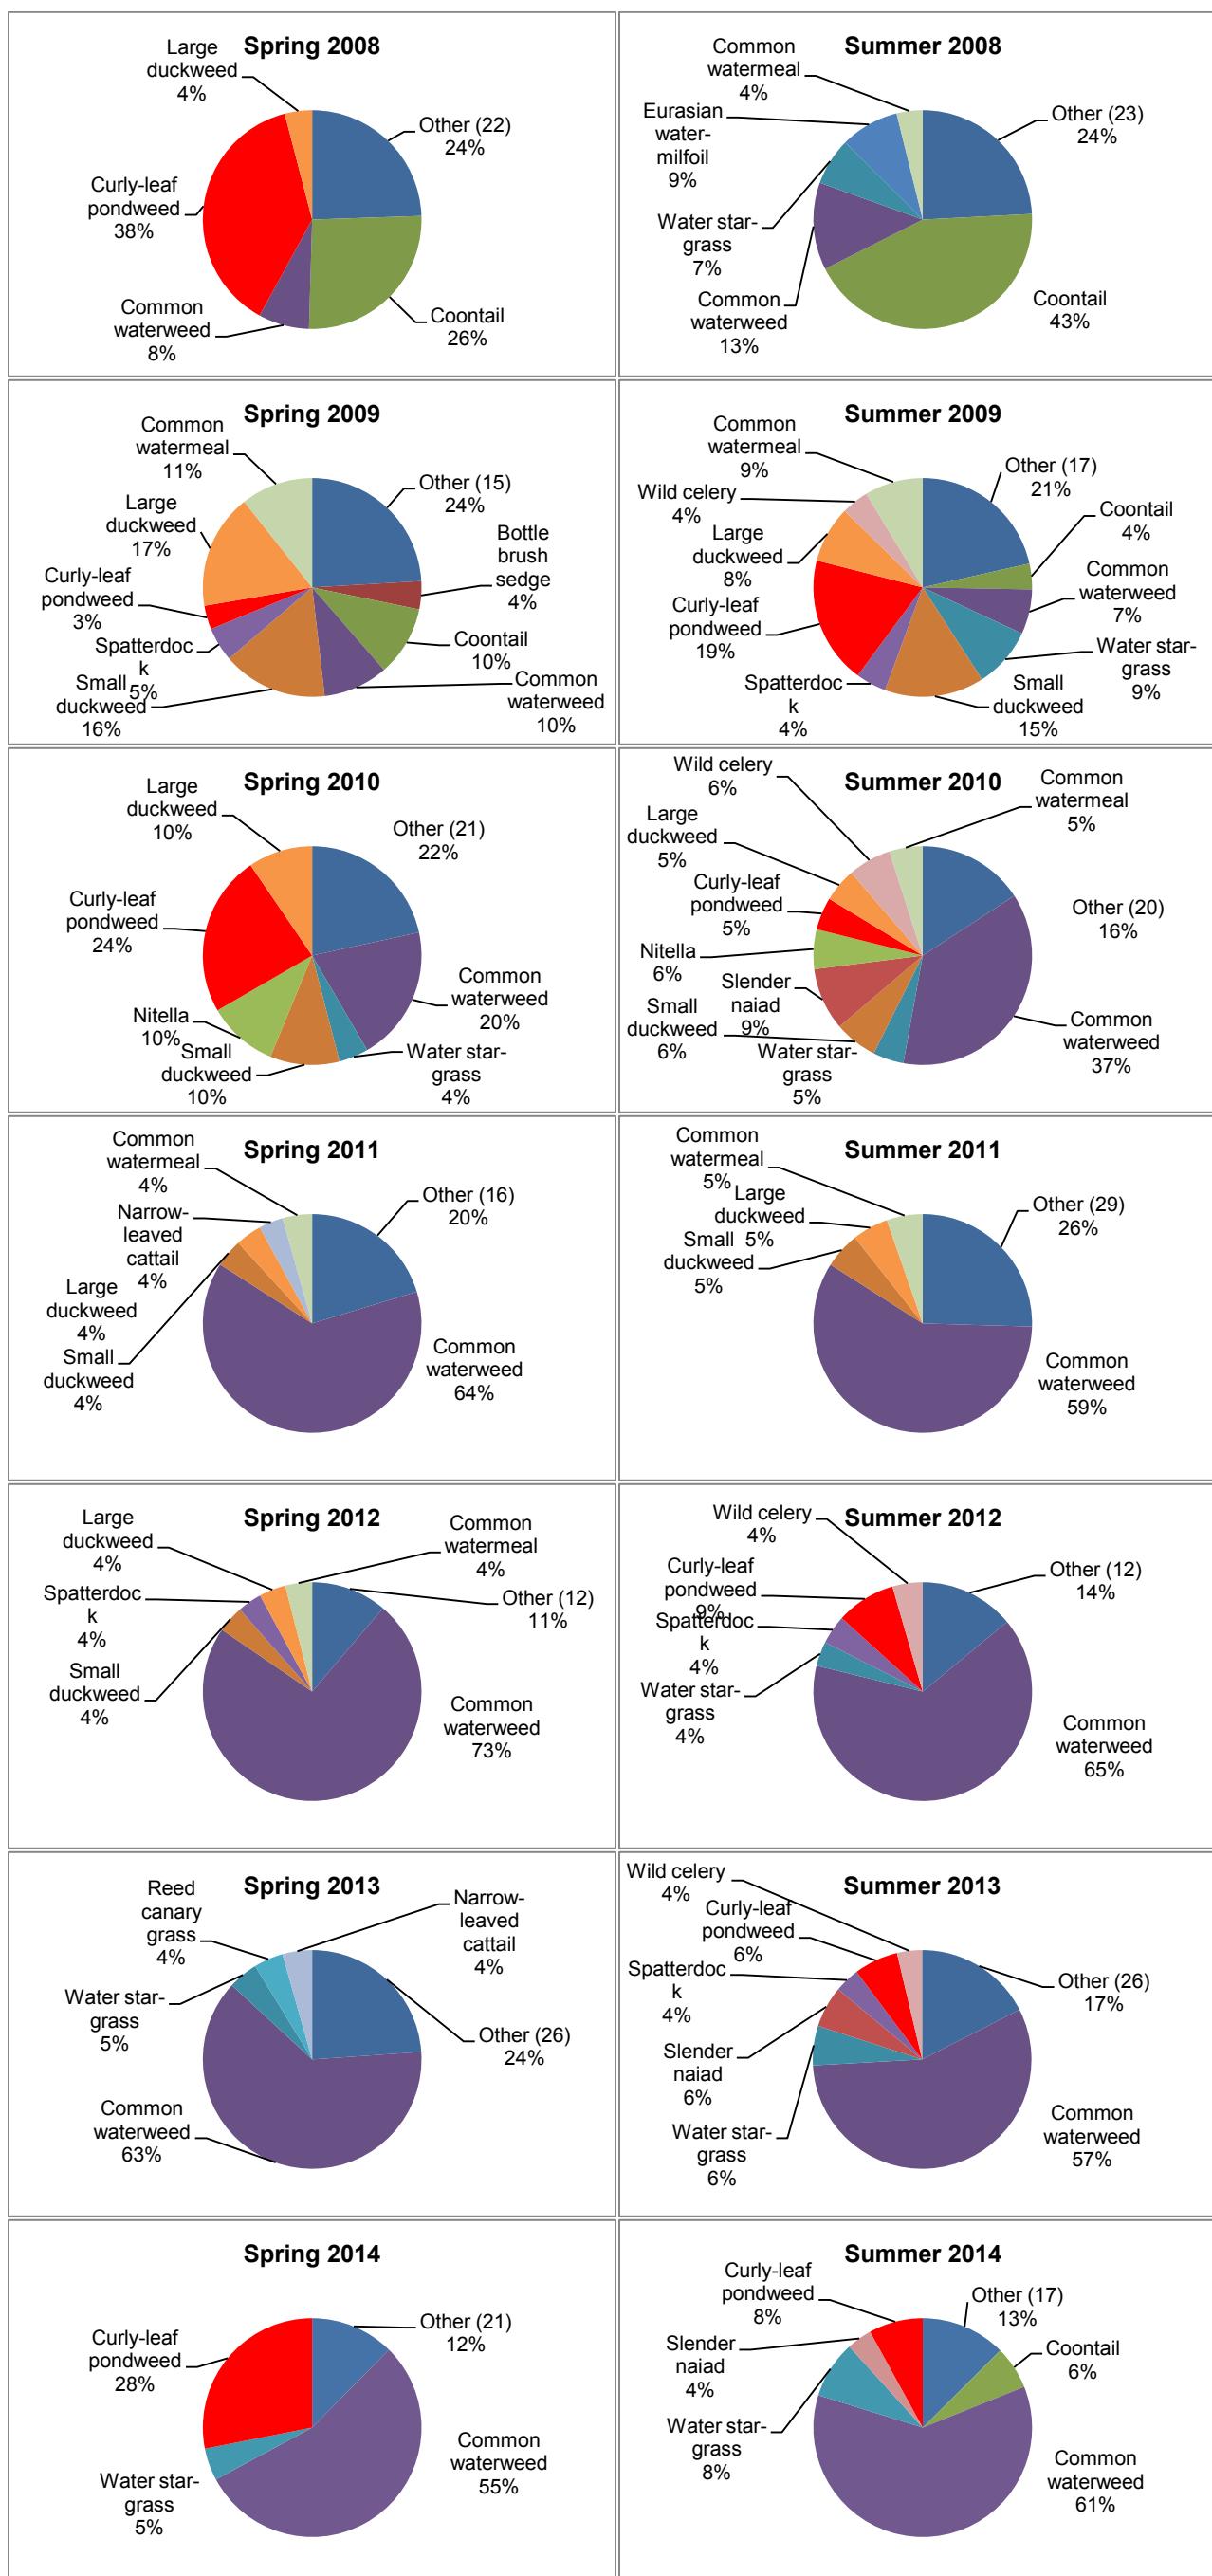

Figure 6. Dominance values of aquatic plant community

Half Moon Lake's FQI and AMCI values were compared to lakes in Wisconsin (WI) and the Driftless Area (DMR) region. Box plots illustrate where Half Moon Lake falls on the continuum of values. The graphic to the right illustrates the box plot. The minimum and maximum represent the lowest and highest values. 25% of lakes fall above and below the upper and lower quartile marks and 50% of lakes fall above and below the median value.
