

**SUMMARY REPORT:
RAFT CHANNEL AREA, POOL 8 ISLANDS, PHASE III, STAGE II PRE-PROJECT FISHERIES
EVALUATION, POOL 8, 2007, 2008.**

Wisconsin Department of Natural Resources,
Mississippi River Fisheries Team, La Crosse, WI.

25 June 2009

PURPOSE

The purpose of this work is to describe the baseline fisheries community prior to completion of the Pool 8 Islands, Phase III, Stage II habitat rehabilitation and enhance project Navigation Pool 8 of the Mississippi River.

METHODS

The Pool 8 Islands, Phase III, Stage II Habitat Rehabilitation and Enhancement Project is located in Navigation Pool 8 of the upper Mississippi River (Figure 1). The study area is located in the downstream one-third of the pool formed by Lock and Dam 8 and had a total water surface area of 19,676 acres as of the year 2002.

Stage II has a total of 12 planned islands. Construction of four West Islands and three of the North Islands began in spring 2008. Construction of four seed islands and one North Island began in July 2007 and was completed in summer 2008. In the fall of 2008, all islands were in place, but additions to these islands is planned for 2009. By August 2009, construction of all islands in Stage II will be completed.

Standard Upper Mississippi River Conservation Committee (UMRCC) fyke nets were set by fisheries personnel. These fyke nets had a 50ft floating lead line, 3ft high and 6ft wide frame, and had a 0.75 inch bar mesh. During 2007, nets were set at randomly selected locations. This was done using an ArcView GIS 3.3® random point generating script and the Long Term Resource Monitoring Program (http://www.umesc.usgs.gov/data_library.html) 1998 bathymetric data (Rogala, 1997). Points were generated only in locations that had 0.3 to 1.1m water depth as measured at the middle of the net. During 2008, fyke netting locations were chosen in a similar fashion, except that we ensured that the about same proportion of nets were set on a shoreline as were set in 2007 (2 of 9 in 2007 and 3 of 9 in 2008). Nine locations were chosen each of the two sampling years. During both years, if a location was found to be unsuitable for fyke netting, a randomly selected alternate location was chosen instead.

Fyke nets were fished from October 15 through 19, 2007 and October 13 through 17, 2008 (Figures 2 and 3, Table 1). These nets fished a total of 27.503 and 35.799 net-days in 2007 and 2008, respectively. Nets were emptied every day during which all fish were removed.

In addition to fyke netting, an 18 foot-long welded aluminum flat-bottomed maxi-boom electro shocking boat equipped with a Wisconsin Box was used on approximately 10 minute day-time runs. Two booms extended 8 feet from the bow and the box controls were adjusted to produce 16 amps. Runs were randomly chosen from available locations that were between 0.4 and 1.6m deep. Randomly selected runs that were too shallow or too deep or otherwise adverse to electro shocking were not done and replaced with another randomly selected run. In 2007, a total of 44 runs were done during 7.331 hours of sampling (Figure 4) done on five days from October 23 through October 29. During 2008, we shocked a total of 42 runs during 7.014 hours (Figure 5) on four days from October 21 through October 24. For both gears, all fish were counted. Of these fish, all pan fish and game fish were measured by total length.

FINDINGS

The mean daily ambient water temperatures during 2007 sampling was 12.6°C and generally declined over the sampling period (Table 3). During sampling, the water surface elevation measured at the Brownsville, Minnesota, gage changed as much as 1.06 feet. The mean daily flow in cubic feet per second was 64353 and fluctuated as much as 22800 cubic feet per second.

The mean daily ambient water temperatures during 2008 sampling was 12.0°C and generally declined over the sampling period (Table 3). During sampling, the water surface elevation measured at the Brownsville, Minnesota gage changed as much as 0.25 feet. The mean daily flow in cubic feet per second was 21209 and fluctuated as much as 8500 cubic feet per second.

Catch per Effort, Fyke Netting

During 2007 fyke netting, a total of 23 fish species and 2003 individuals were recorded. The most common fish recorded was gizzard shad (37.64% of the total catch) followed by bluegill (32.80%), black crappie (7.49%) and freshwater drum (6.54%) (Table 4). Mean catch per net-day for all species combined was 71.26 (standard deviation = 59.35, n = 27) during 27.503 net days of fishing and varied from a minimum of 2.97 to a maximum of 223.06. Catch rates for individual species are given in Table 4.

During 2008 fyke netting, a total of 23 fish species and one hybrid were found among a total of 1459 individuals. The most common fish recorded was bluegill (50.93% of the total catch) followed by black crappie (14.46%), largemouth bass (9.53%) and pumpkinseed (7.54%) (Table 5). The greatest change in relative abundance between the years was for gizzard shad. It dropped from 37.64% of the catch in 2007 to 1.78% of the catch in 2008. Mean catch per net-day for all species combined was 41.10 (standard deviation = 47.63, n = 36) during 35.799 net days of fishing and varied from a minimum of 1.97 to a maximum of 194.56. Catch rates for individual species are given in Table 5.

Fyke net catch rates between 2007 (71.26) and 2008 (41.10) for all species combined (Table 6) were significantly different ($p=0.0289$). Since gizzard shad abundance dropped drastically from 2007 to 2008, we tested fyke net catch rates between these years for all species combined excluding gizzard shad. Without this fish, catch rates between 2007 (44.05 fish/net-day, standard deviation = 41.68, n=27) were not significantly different ($p=0.7493$) from 2008 rates (40.37 fish/net-day, standard deviation = 47.43, n=36) (Table 7). This suggests that the difference in total fish catch rates between these years (30.16 fish/net-day) was due to a large inter-annual change in the gizzard shad catch rate.

Catch per Effort, Electro Shocking

During 2007 electro-shocking, at least 34 fish species and one hybrid were among 4319 individuals recorded. The most common fish recorded was gizzard shad (73.25% of the total catch) followed by bluegill (8.75%), largemouth bass (5.17%) and shorthead redhorse (2.2%) (Table 8). Mean catch per hour for all species combined was 669.99 (standard deviation = 1361.24, n = 44) during 7.331 total hours of fishing and varied from a minimum of 11.98 to a maximum of 8431.14. Catch rates for individual species are given in Table 8.

During 2008 electro-shocking, at least 27 fish species were found among a total of 755 individuals. The most common fish recorded was largemouth bass (34.44% of the total catch) followed by bluegill (32.58%), northern pike (7.15%) and yellow perch (6.75%) (Table 9). The greatest change in relative abundance between the years was for gizzard shad. It dropped from 73.25% of the catch in 2007 to 0.79% of the catch in 2008. Mean catch per hour for all species combined was 107.64 (standard deviation = 112.33, n = 42) during 7.014 total hours of fishing and varied from a minimum of 11.98 to a maximum of 514.97. Catch rates for individual species are given in Table 9.

Electro-shocking catch rates, in number of fish per hour, between 2007 (669.99) and 2008 (107.64) for all species combined (Table 10) were significantly different ($p=0.0092$). Since gizzard shad abundance dropped drastically from 2007 to 2008, we tested electro shocking catch rates between these years for all species combined excluding gizzard shad. As opposed to fyke netting, electro shocking without this fish, catch

rates between 2007 (179.43 fish/hour, standard deviation = 187.74, n=44) and 2008 rates (106.79 fish/hour, standard deviation = 112.53, n=42) were not significantly different ($p=0.0333$) (Table 11). This suggests that, unlike fyke netting, the difference in total fish catch rates between these years (562.35 fish/hour) was influenced by a decline in gizzard shad catch rate but was not important enough to significantly change that rate.

Length Distributions

For fyke netted 2007 and 2008 fishes where there were sufficient numbers, we generated total length distributions and mean total lengths (Figures 6 through 17). Of the five fishes tested for differences in mean total length among years (black crappie, bluegill, largemouth bass, pumpkinseed and rock bass) only pumpkinseed was significantly different. In 2008, pumpkinseeds were 0.36 inches smaller than those from 2007 ($P=0.0034$).

For electro shocked 2007 and 2008 fishes where there were sufficient numbers, we generated total length distributions and mean total lengths (Figures 18 through 27). Of the five fishes tested for differences in mean total length among years (black crappie, bluegill, largemouth bass, pumpkinseed and yellow perch) only bluegill was significantly different. In 2008, bluegills were 0.56 inches larger than those from 2007 ($p<0.0001$).

CONCLUSIONS

Combined species fyke net catch rates from 2007 were 71.26 fish/net-day. In 2008, combined species catch rate was significantly lower at 41.10 fish/net-day. Substantially lower abundance of gizzard shad accounted for this difference from 2007 to 2008. Without this fish, 2007 catch rates were 44.05 fish/net-day, compared with 40.37 fish/net-day in 2008 and were not statistically different. In the northern Midwest, it is not unusual to observe gizzard shad populations fluctuate greatly. In Wisconsin, they are on the northern end of their geographic range and die in large numbers during long, cold, snowy winters. During 2007 and 2008, lower populations were observed in other WDNR investigations on the Mississippi River.

Combined species electro shocking catch rates from 2007 were 669.99 fish/hour. In 2008, combined species catch rate was significantly lower at 107.64 fish/hour. Unlike fyke netting results, substantially lower abundance of gizzard shad in 2008 influenced this inter-annual difference but did not determine it.

Mean total length of selected species were generally the same among years. Only fyke netted pumpkinseeds, which were 0.36 inches smaller in 2008, and electro shocked bluegills, which were 0.56 inches larger in 2008 changed.

RECOMMENDATIONS

1. Continue to monitor the fisheries community in the Pool 8 Islands, Phase III, Stage II habitat rehabilitation and enhancement project in Navigation Pool 8 of the Mississippi River. Monitoring should continue for several years after the 2009 completion of this project.
2. Monitoring results should be compared with ongoing Lake Assessment sampling results, which could serve as a reference condition.
