Mr. David J. Kafura WISCONSIN DEPARTMENT OF NATURAL RESOURCES Northwest District Headquarters Box 309 Spooner, WI 54801

Dear Dave:

RE: Penta Wood Products - Phase II Report

Please find enclosed three (3) copies of the Penta Wood Products - Phase II Report for your review and comment.

Upon completion of the Departments review of this report, please contact us to arrange a date and time to discuss the conclusions and recommendations presented in this report.

Should you have any questions, please do not hesitate to contact us.

Yours Very Truly,

1.5. Mock

1.0 INTRODUCTION

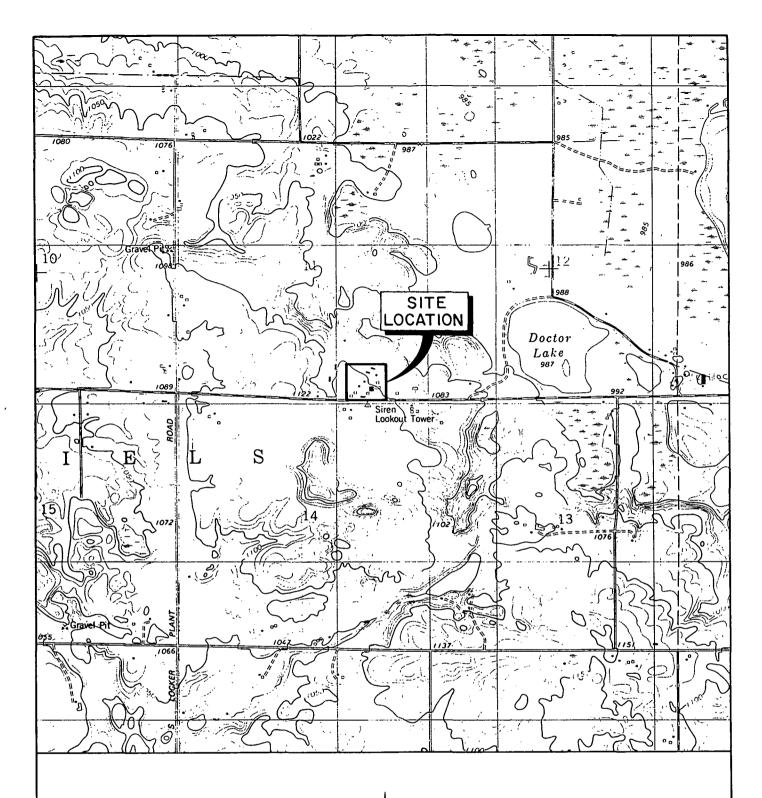

Penta Wood Products Inc. (PWP) is an operating wood treating facility located in Siren, Wisconsin, which has treated wood products since the 1950s with pentachlorophenol. Since 1975, PWP has also treated with chemonite (containing arsenic, copper and zinc). Figure 1 shows the location of the PWP site.

In 1987, the Wisconsin Department of Natural Resources (DNR) requested that PWP assess the environmental conditions at the Site as a result of a DNR study of Site conditions. Subsequently, Conestoga-Rovers and Associates (CRA) was retained by PWP to develop and implement a phased work plan to assess potential sources of contamination and to characterize the nature and extent of soil and groundwater contamination.

On August 21, 1987, on behalf of PWP, CRA submitted a work plan to assess PWP's operations. The findings of this work plan were outlined in a report titled "Site Evaluation - Penta Wood Products" submitted to the DNR in July 1988.

In this report, recommendations were made for further work at the PWP Site. This Phase II Scope of Work was modified by the DNR in two letters dated October 27, 1988, and March 7, 1989. The Phase II field work was completed during the spring and summer of 1989.

This report presents the results of the Phase II work plan.

2.0 BACKGROUND

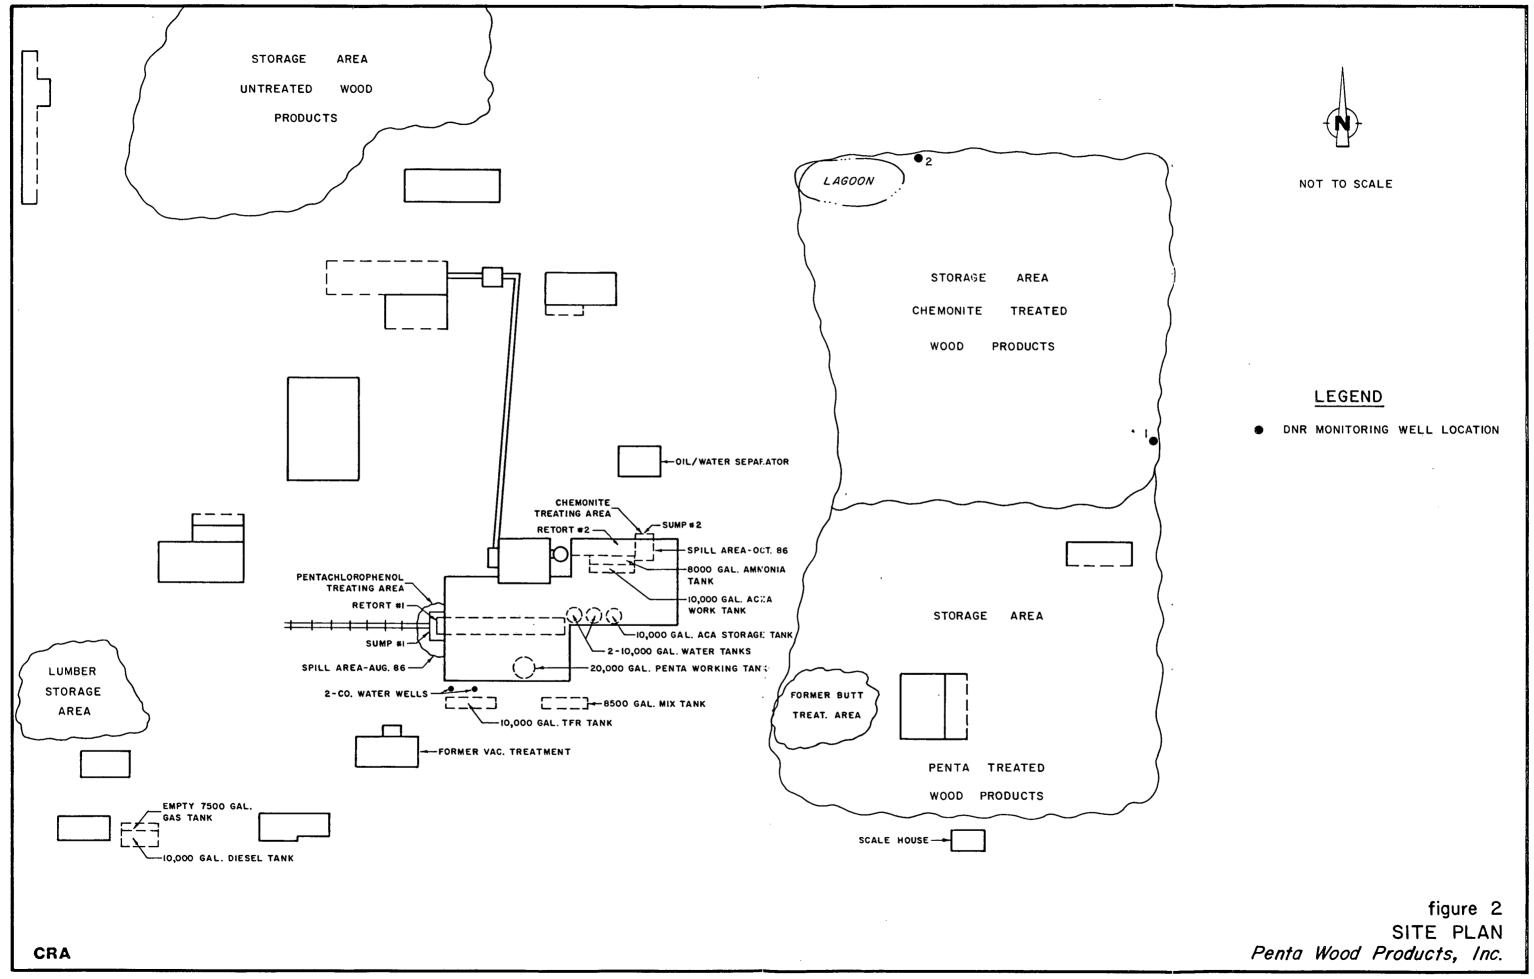

A detailed history of PWP's plant operations and past spills and response actions are presented in the "Scope of Work" report dated August 21, 1987, and the "Site Evaluation" report dated July 21, 1988. This history is based on information provided by PWP. Figure 2 illustrates Site features.

2.1 PHASE I RESULTS

The results of the Phase I investigation indicated that the groundwater under the Site, below the hard pan, was contaminated with pentachlorophenol (PCP). The results also indicated that the surficial soils around the oil/water separator and the chemonite treating area have elevated concentrations of PCP and metals. However, the metals were not considered a potential source of groundwater contamination. The Phase II work plan outlined additional work to be done to further define the extent of this contamination.

2.2 PHASE II WORK PLAN

The Phase II work plan was outlined in Section 6.0 of the "Site Evaluation" report dated July 21, 1988. This work plan was modified based on comments provided by the DNR in two letters dated October 27, 1988, and March 7, 1989. This modified work plan was finalized in CRA's letter dated April 13, 1989.

3.0 PHASE II RESULTS

3.1 SOIL SAMPLING

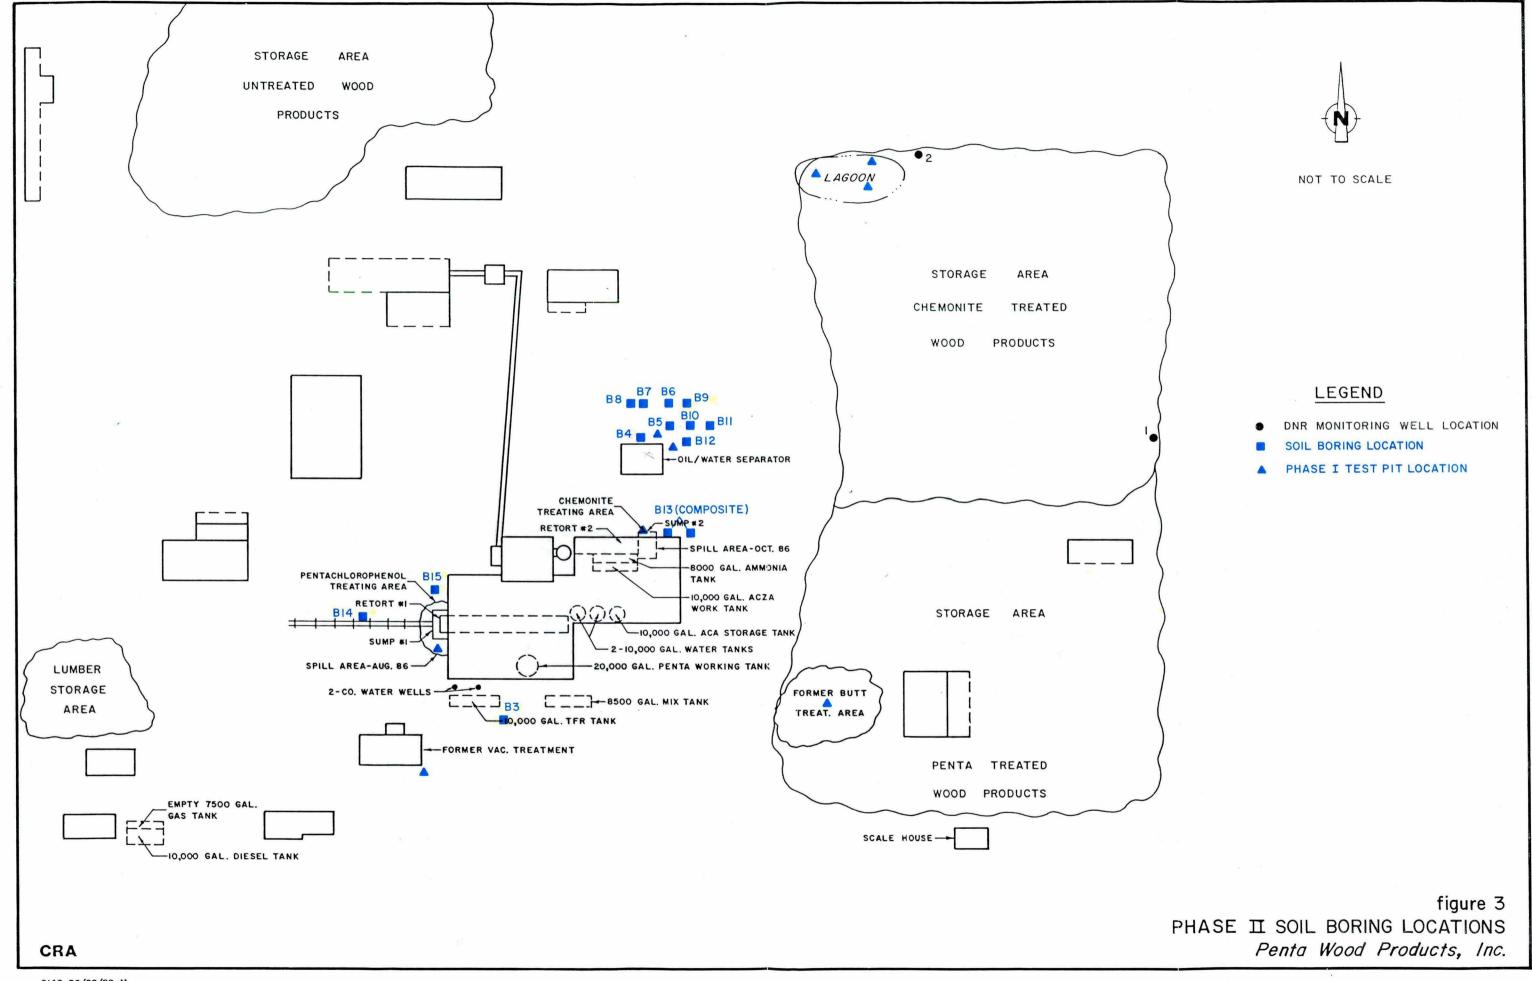

During the week of June 12, 1989, the field work commenced at the PWP Site. Wisconsin Test Drilling (WTD) mobilized a Mobile Drill D-50 soils auger drill rig to the Site. This work involved drilling and sampling at two deep borings and 12 shallow borings.

Two soil borings were completed at locations shown on Figure 3. The purpose of these soil borings was to better define the soil stratigraphy of the Site and to allow for the installation of two monitoring wells as outlined in the Phase II Scope of Work. The overburden stratigraphic logs for these borings are presented in Appendix A. Upon completing these borings it was discovered that there was no groundwater or any evidence of groundwater on top of the hard pan unit. Therefore, after discussing this with the DNR, no monitoring wells were installed.

3.1.1 Production Well Area - Deep Boring

Boring B3, which is located very close to the company production wells, showed no evidence of contamination (i.e. visual or olfactory), hence, chemical soil samples were not taken at this soil boring. The hard pan

THE ASSUMPTION
THEY WERE GOINGT
TO DO ANALYSIS.
TO DO ANALYSIS.

unit was encountered at a depth of 135 feet below ground surface which is consistent with the soil stratigraphy recorded on the water well logs for PWP's production wells.

3.1.2 Oil/Water Separator Deep Boring

LONN I I FELT IT WAS MORE LIKE 30-35 FT.

Boring B4, which is located on the north side of the oil/water separator, did show evidence of soil contamination to a depth of approximately 15 feet below ground surface. The top 10 feet had both an "oily" film and an odor. The split spoon sample at 15 feet below ground surface had a slight odor, but no "oily" appearance. A sample was taken at a depth of 20 feet BGS and analyzed for PCP. This and all samples collected for chemical analysis were taken from a precleaned split spoon. The results of these analyses are presented in Table 1 and the analytical lab report is presented in Appendix B. PCP was not detected below 15 feet.

The hard pan at B4 was found at a depth of 110 feet below ground surface. This correlates to approximately the same elevation found at B3.

3.1.3 Oil/Water Separator Shallow Borings

Eight additional shallow borings were conducted around the north side of the oil/water separator. This area was selected due to past

¹The cleaning sequence consisted of a thorough scrubbing in trisodiumphosphate (TSP) followed by a solvent rinse of methanol, hexane and methanol. The spoon was then rinsed with distilled water.

spills in the area and with consideration of drainage. The location of these borings are shown on Figure 4. Samples taken for PCP chemical analysis were taken from these soil borings at depths shown in Table 1. Also shown in this table are the analytical results for these soil samples. Appendix B contains the lab reports. The only soil boring that had detectable concentrations of PCP was boring B9. At this boring, the sample taken at 2 feet BGS had a concentration of 2,100 mg/kg and the 5 foot sample had a concentration of 170 mg/kg. The sample at 10 feet BGS was non-detect (ND).

3.1.4 Chemonite Treating Area

As requested by the DNR, chemical soil samples from boring B13 were taken at greater depths (5 feet and 10 feet) in this area. Figure 3 shows the location of these borings. A composite sample was taken from each boring at a depth of 5 feet and at 10 feet below ground surface. These samples were analyzed for the target metals of concern: arsenic, copper and zinc and for pentachlorophenol. The analytical results are summarized on Table 1.

Appendix B contains the lab reports. A sample was collected and held for potential analysis by EP Toxicity Leach Testing procedures. In addition, deeper borings were conducted to provide a metals profile with depth. Analytical results for metals from both Phase I and II were reviewed and indicate that elevated levels of metals above background were limited to a depth of approximately 3 feet and metals concentrations at depths of 5 and 10 feet were found to be similar

OIL/WATER SEPARATOR

LEGEND

5'(ND) DEPTH OF SAMPLE (PCP CONC. IN mg/kg

figure 4
SOIL BORING LOCATIONS
-OIL/WATER SEPARATOR
Penta Wood Products, Inc.

CRA

to background concentration. As such, an EP Toxicity Leach test was not conducted on these samples because of the very low level presence of metals.

3.1.3 Pentachlorophenol Treating Area

As requested by the DNR, a boring, B14, was conducted in an area along the railroad tracks that lead into the penta treating retort cylinder. The DNR originally requested a test trench in this area, however, due to the potential for track disturbance, it was decided by both CRA and the DNR that a soil boring would be more appropriate. This soil boring location is shown on Figure 3. Chemical soil samples were taken at a depth of 5 and 10 feet below ground surface and analyzed for pentachlorophenol. These results are summarized on Table 1 and the actual lab reports are contained in Appendix B. Neither of these soil samples had concentrations of pentachlorophenol above the method detection limit.

During a field site inspection, the DNR expressed a concern about an area just north of the pentachlorophenol treating area. The retaining wall north of the pentachlorophenol retort sump has a PVC pipe coming out of the side of the wall. Upon further inspection it was found that this pipe did connect to the sump. This pipe was plugged on the sump end with sand. The DNR was concerned that this pipe may have drained treating solution out of the sump. It was decided that a soil boring, B15, should be done in this area. This location is shown on Figure 3. Due to the number of overhead utility lines and plant piping, a hand auger was used to take a chemical soil sample at a depth of

5 feet below ground surface. The analytical results are summarized in Table 1 and the lab reports are contained in Appendix B. The concentration of pentachlorophenol in this soil sample was non-detect.

3.3 GROUNDWATER SAMPLING - PRODUCTION WELL

During this field investigation, a water sample was taken from PWP's production wells. The faucet outside the treating building was turned on and the system was allowed to purge for 40 minutes to flush the lines to assure that a representative water sample was taken. This groundwater sample was analyzed for pentachlorophenol. The lab reports are contained in Appendix B. This groundwater sample showed pentachlorophenol at a concentration of 1,300 μ g/L, which is consistent with concentrations reported previously.

3.4 WOOD CHIP/BOILER ASH SOIL SAMPLE

The DNR, in their letter dated March 7, 1989, requested a sample of ash be taken and analyzed for octachlorodibenzo-p-dioxin. CRA interviewed several PWP employees and were told that there was only one area where the boiler ash was deposited. This area is outside the door from the boiler room. After discussing this with the DNR, it was decided that a composite sample be taken from this ash pile. Twenty hand auger holes were conducted in

and on top of the ash pile to obtain a representative cross sectional sample. This sample was submitted for a complete (C1 through C8 congeners) dioxin analysis. The following evaluation was conducted by Dr. Paul Nees who is CRA's toxicologist.

NOW COMES THE DANCE AROUND THE RESULTS. SOMEBODY IS TRYING TO DIRTY THE WATER. DR.

3.4.1 Evaluation of Chlorinated Dibenzoparadioxin (PCDD)
Reported in a Soil/Ash Sample from Penta Wood Products Site

A composite sample of ash/soil was analyzed for PCDDs and the levels of tetra-, penta-, hexa- and octachlorinated isomers reported. The analyses were conducted by International Technology Corporation (IT) Analytical Services and reported July 27, 1989, to CRA. The sample was identified as Ash/Soil, Project ID 2140.

Evaluation Procedure

The evaluation of mixtures of PCDDs is frequently necessary but only a few of the 75 PCDD isomers have been studied sufficiently to conduct adequate risk assessments on the individual isomers. The isomers vary extensively with respect to their toxic potency although they all produce qualitatively similar toxic effects.

One isomer, 2,3,7,8-tetrachlorodibenzodioxon (2,3,7,8-TCDD), which is the most toxic, has been studied extensively. Comparative studies have been conducted on the other PCDD cogeners to allow estimates of their toxicity in comparison to 2,3,7,8-TCDD. From these comparisons, toxicity equivalence factors (TEFs) have been developed. See

Table 2. Multiplying the TEF times the concentration of the appropriate congener yields the concentration of 2,3,7,8-TCDD comparable to the congener concentration on a toxicity basis. With all cogeners converted to a 2,3,7,8-TCDD equivalent base, the concentrations can be added to determine the total 2,3,7,8-TCDD equivalent concentration and this concentration evaluated for potential health and environmental effects. This procedure and the TEFs have been developed by the Chlorinated Dioxin Work Group and published in a position document "Interim Task Assessment Procedures for Mixtures of Chlorinated-Dibenzodioxins and -Dibenzofurans (CDDs and CDFs)". This documented was updated April 1986.2

Evaluation and Discussion

Table 3 presents the reported PCDD concentrations for the sample and the 2,3,7,8-TCDD toxicity equivalent concentrations. Three equivalence values are presented for each homologous group (tetra-, penta-, hexa-, etc). The "worst case" set of values assumes all the isomers in the homologous group contain 2,3,7,8 position substitutions. 2,3,7,8 cogeners are considered more toxic than non-2,3,7,8 cogeners and are therefore given high TEF factors. The "best case" set of values assumes none of the isomers reported in the homologous group contains the 2,3,7,8 substitution. For the "more likely case", it is assumed that each isomer in the homologous group is present at equal

TO THIS FACILITY - MAKE A MULTIDISCIPLINARY "PROJECT" OUT OF THEM?

AN 10/31/89

concentrations. In this evaluation where the original source of the PCDDs is not identified, the "most likely case" seems most appropriate. For the sake of completeness, values have been calculated and are presented for all three assumptions.

The total equivalent concentrations of 2,3,7,8-TCDD for the sample was 0.331, 0.039 and 0.003 ug/kg for worst, more likely and best case, respectively. These concentrations all are less than 1 ppb (ug/kg) guideline concentrations established by the Center for Disease Control (CDC) for 2,3,7,8-TCDD in soil in a residential area.³ In the reference the author states: "We therefore conclude that a soil level of 1 ppb TCDD (2,3,7,8-TCDD) in residential areas is a reasonable level at which to express TCDD (2,3,7,8-TCDD) below 1 ppb are, for practical purposes considered not to reach a level of concern". With respect to commercial areas, CDC concludes: "Since these total doses for all routes are so much smaller than in residential areas, a level of concern may not necessarily be reached unless levels are several fold or more above 1 ppb".

Conclusion

The evaluation proposed by the Cancer Work Group Policy Document and the CDC guidelines for levels of 2,3,7,8-TCDD which would be a level of concern in soil from residential and industrial areas, support the conclusion that the reported concentrations of PCDDs in an ash/soil sample are not levels of public health concern, regardless of the disposition of the ash/soil.

³Kimbrough, R.D., et.al. Health Implications of 2,3,7,8-Tetrachlorodibenzodioxin (TCDD) Contamination of Residential Soil. Journal of Toxicology and Environmental Health, 14:47-93. 1984

4.0 CONCLUSIONS

Based on the findings of the Phase II Site Evaluation, the following conclusions are made:

- There is no perched water in the upper sand unit around the treating/ production areas at the time of this investigation.
- Groundwater in the lower sands below the hard pan continue to show elevated levels of pentachlorophenol. This water is used for production purposes, but use of this well as a drinking water source was discontinued in 1988.
- 3. Surface soils in and around the PWP production area are contaminated with pentachlorophenol. These areas include the oil/water separator building, the pentachlorophenol treating area and the chemonite treating area. This contamination appears to be limited to the top few feet of sand within these areas.
- 4. Metals concentrations in the surface soil around the chemonite treating area show elevated levels of the target metals. The soils below 3 feet below ground surface have background metals concentrations.
 - The boiler ash pile does show the presence of octachlorodibenzo-p-dioxin. When this dioxin is converted to a toxic equivalency as 2,3,7,8-TCDD, it is found that there is no significant health risk associated with the very low level dioxins present in the ash pile.

5.0 SCOPE OF WORK - PHASE III

5.1 PURPOSE

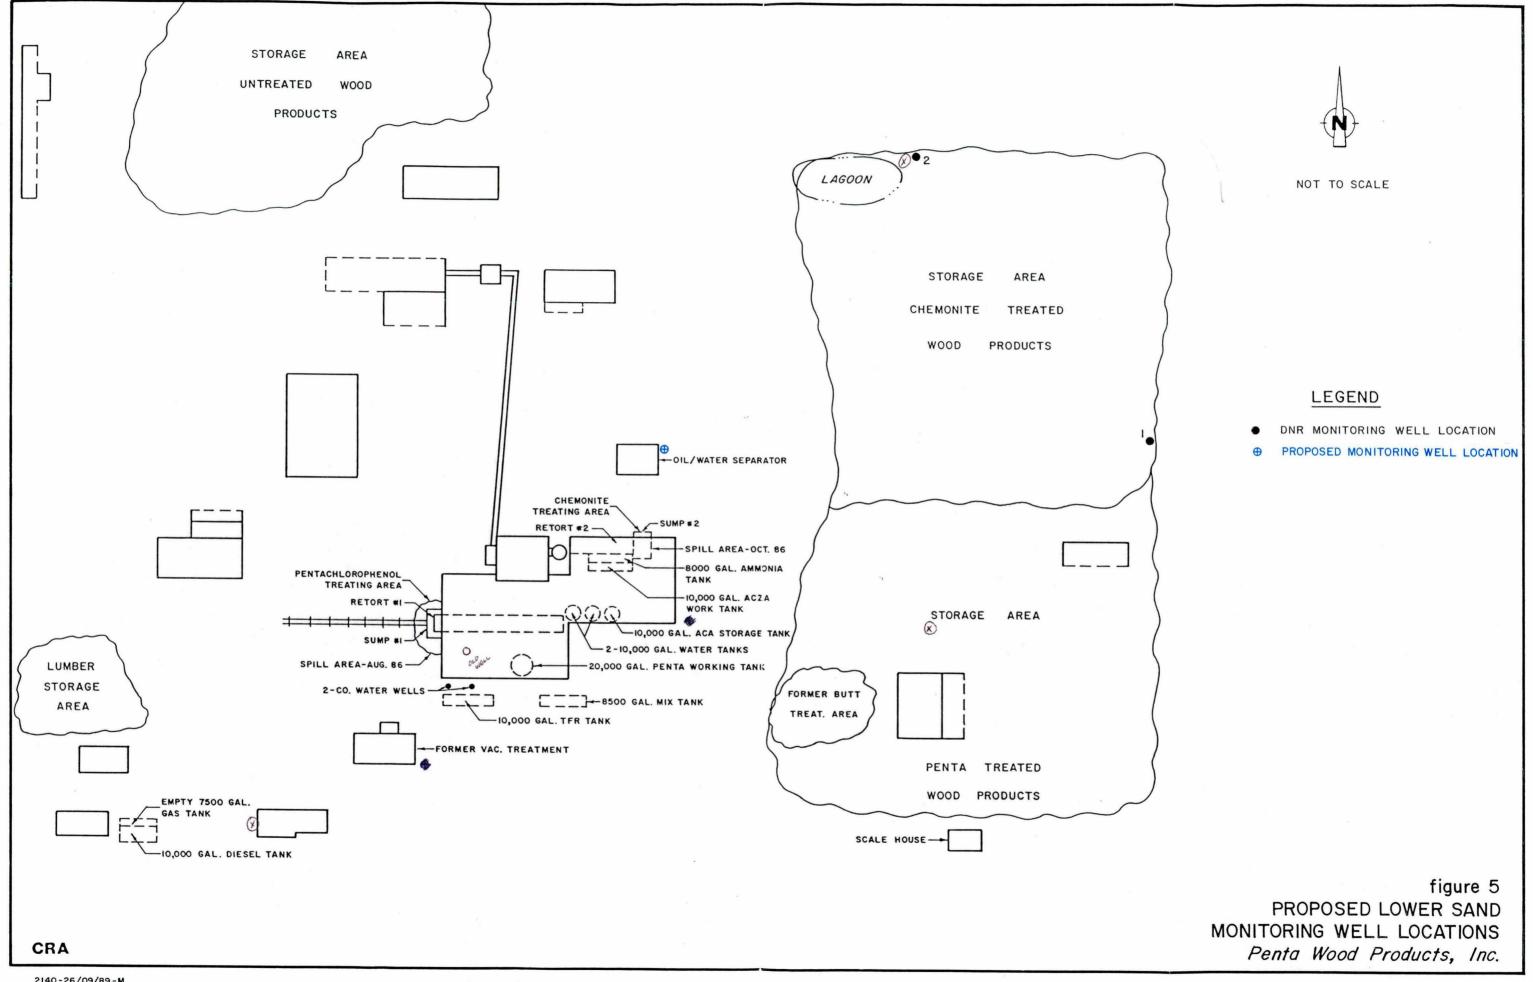

Phases I and II of this investigation have identified the presence of contamination at the PWP Site. The following work items are required to further define surface and subsurface contamination at the Site.

5.2 PHASE III WORK PLAN

5.2.1 Lower Sand Aquifer Wells

CRA proposes that three lower sand wells be installed at the location shown in Figure 5. These wells are required to determine groundwater flow direction in the lower sand aquifer and to determine whether or not purging from the company production wells are in fact containing the pentachlorophenol present in the lower sand aquifer.

These wells would be installed using cable tool drilling techniques. They will be installed to the same depth as the companies production wells. After the installations have been completed the wells will be developed and stabilized. A groundwater sample will be taken from each well and analyzed for pentachlorophenol. Groundwater elevations will also be calculated to determine groundwater flow directions in the lower sand aquifer.

5.2.2 Production Well Area/Underground Storage Tanks

There are two underground storage tanks in the near vicinity of the company's production wells. The 8,500 gallon mix tank has been excavated and placed above ground in a containment building. The 10,000 gallon transfer tank is still under ground. This tank was pumped dry and filled with sand. The physical integrity of this tank is unknown. Therefore, CRA proposes that this tank be excavated and checked for former leakage. Three soil samples will be collected directly beneath the tank and analyzed for PCP.

5.2.3 Oil/Water Separator

CRA proposes that a hand auger borehole be advanced inside the building as deep as practical (at least 10 feet) to obtain a chemical soil sample. This chemical data is critical in determining how much of an impact this building has had on the soils under this building. Further delineation of soil contamination around the boring B9 area is also proposed.

APPENDIX B ANALYTICAL REPORTS

ANALYTICAL SERVICES

JUL 31 89

CERTIFICATE OF ANALYSIS

Steve Mockenhaupt

CRA, Inc.

382 W. Country Road - D

St. Paul, MN 55112

DATE: July 27, 1989

PROJECT NUMBER: CRA482180

This is the Certificate of Analysis for the following sample:

Client Project ID:

2140

Date Received by Lab:

July 6, 1989

Number of Samples:

One (1)

Sample Type:

Ash/Soil

I. <u>Introduction/Case Narrative</u>

One (1) ash/soil sample was received 07-06-89 for the analysis of both isomer specific 2,3,7,8-TCDD and total tetra through octa (Cl₄-Cl₈) dioxin homologs. The sample and blank were spiked with an internal standard mixture containing 50 ng each of ¹³C-2,3,7,8-TCDD, ¹³C-PeCDD, ¹³C-HxCDD, ¹³C-HpCDD and ¹³C-OCDD. The sample and blank were extracted and cleaned up using a modified version of the EPA reference method described in "RCRA SW-846, Method 8280," revised September, 1986. Extracts were analyzed by GC/MS operating in the selected ion monitoring mode for enhanced sensitivity.

II. Analytical Results/Methodology

SAMPLE PREPARATION

A ten (10) gram aliquot of the ash/soil and 10 grams of sodium sulfate (for the blank) were weighed into separate soxhlet thimbles. The sample and blank were spiked with the internal standard mixture and allowed to stand overnight for equilibration followed by a soxhlet extraction with benzene for sixteen hours. The resulting extracts were filtered into a KD flask and the volume reduced to approximately 1 ml.

SAMPLE CLEANUP

To aid in the removal of chemical interferences, the sample and blank were cleaned up using dual column chromatography consisting of an acid-modified silica gel column followed by a neutral alumina column. Detailed descriptions of these cleanup techniques can be found in Option A of the U.S. Environmental Protection Agency, Region VII Protocol for "The Determination Of 2,3,7,8-TCDD In Soil And Sediment", revised September, 1983. Final extracts were concentrated to near dryness and raised to 50 μ l with 25 ng 13 C-1,2,3,4-TCDD and 25 ng 13 C-1,2,3,7,8,9-HxCDD which were used as recovery standards.

GC/MS ANALYSIS

Isomer Specific TCDD - The sample extracts were analyzed using HRGC/LRMS scanning in the selected ion monitoring mode for enhanced sensitivity. The column used for this isomer specific analysis was a 60 m SP-2331 fused silica capillary column. Before acquisition of the sample data, a seven isomer performance mixture containing the six most closely eluting TCDD isomers was analyzed.

In addition, a seven point calibration plot was analyzed. The mean response factors obtained from this seven point calibration were used for all subsequent calculations. The shift standard, analyzed on the same day as the sample, produced a response factor within 10% of the seven point curve for TCDD. Percent recovery is reported by comparing ¹³C-2,3,7,8-TCDD to ¹³C-1,2,3,4-TCDD.

(615) 690-3211

Project ID No.: CRA482180

Total Dioxin - The sample and blank were analyzed for total dioxin homologs from $\mathrm{Cl_4}\text{-}\mathrm{Cl_8}$. The analytical approach employed by ITAS for the determination of total dioxins is considered semi-quantitative due to the lack of availability of all dioxin isomer standards. The standard analyzed each shift consisted of:

Dioxins

13C-2,3,7,8-TCDD
13C-1,2,3,4-TCDD
13C-1,2,3,7,8-PECDD
13C-1,2,3,6,7,8-HXCDD
13C-1,2,3,7,8,9-HXCDD
13C-1,2,3,4,6,7,8-HPCDD
13C-0CDD
2,3,7,8-TCDD
1,2,3,7,8-PECDD
1,2,3,4,7,8-HXCDD
1,2,3,6,7,8-HXCDD
1,2,3,6,7,8-HXCDD
1,2,3,7,8,9-HXCDD
1,2,3,4,6,7,8-HPCDD
0CDD

Response factors were calculated for each compound in the standard relative to its ¹³C labeled homolog; the same response was assumed applicable to all isomers in each homologous group. A seven point calibration plot was analyzed. The mean response factors obtained from this seven point calibration were used for all subsequent calculations. The shift standard, analyzed on the same day as the sample, produced a response factor within 30% of the multipoint.

The extracts were analyzed using HRGC/LRMS scanning in the selected ion monitoring mode for enhanced sensitivity. The column used for the analysis was a 60 m DB-5 fused silica capillary column.

Page 4 of 6

CRA, Inc.

Date: July 27, 1989

Client Project ID: 2140

IT ANALYTICAL SERVICES 304 DIRECTORS DRIVE KNOXVILLE, TN (615) 690-3211

Project ID No.: CRA482180

GC/MS RESULTS

Isomer Specific TCDD - The results for the isomer specific analysis, shown in Appendix A, are reported in ppb. A detection limit is calculated from 2.5 times the signal in the area of the elution of 13C-TCDD whenever a sample contains no detectable 2,3,7,8-TCDD.

Totals - The results for the totals analysis, shown in Appendix A, are reported in ppb with the total amount of each homologous group calculated. When more than one isomer in a homologous group of dioxin is found, all of the isomers are added together to produce a total homolog result. Detection limits are calculated from 2.5 times signal to noise when a "Not Detected" (ND) is reported. The detection limits are listed in parenthesis.

III. Quality Control

Routine laboratory non-project specific QA/QC was followed. Recoveries for the ¹³C internal standards for each sample are presented with the sample analysis data.
