#### **1. INTRODUCTION**

We prepared this Remedial Action Plan (RAP) to address previously undiscovered, historical polychlorinated biphenyl (PCB) impact in soils at the Tecumseh Falls dewatering facility of the Sheboygan River and Harbor Superfund Site (Site). The PCB impact was discovered during the post remedial sampling of the facility to evaluate the potential that release of sediment during dewatering may have affected the soil. The RAP is also intended to address the Maryland Avenue dewatering facility where lead and polynuclear aromatic hydrocarbons (PAHs) were encountered in shallow soils at concentrations exceeding commercial/industrial preliminary remedial goals (PRGs).

The objective of this RAP is to evaluate the need for remediation at the two dewatering sites and the remedial options to protect human health and the environment. Descriptions of the Site history and known current environmental conditions; data evaluation, proposed remedial methods, reporting; and the estimated project schedule are presented in the following sections.

#### **2. SITE HISTORY AND CURRENT CONDITIONS**

The following subsections summarizes the Site history, current Site conditions, and environmental conditions identified during previous investigations of the Property.

#### **2.1 SITE HISTORY**

Tecumseh, a manufacturer of refrigeration and air conditioning compressors and gasoline engines, was located adjacent to the Sheboygan River in Sheboygan Falls, Wisconsin. Polychlorinated biphenyls (PCBs) were found in sewer lines that lead to the River from Tecumseh and in hydraulic fluids used in Tecumseh Products Company's Diecast Division manufacturing processes. Prior to remediation, the contamination level was high in the sediments immediately surrounding the Tecumseh Falls Site, but decreased in concentration downstream.

The Record of Decision (ROD) listed the risks at the Sheboygan River and Harbor Superfund site to be from the chemicals of concern, metals and PCBs. Metals, PCBs, and polynuclear aromatic hydrocarbons (PAHs) were the as potential chemicals of concern (PCOC). The metals listed as the target of concern for the Remedial Investigations were cadmium, chromium, copper, lead, mercury, nickel, and zinc. Pesticides, dioxins, and dibenzofurans were not present in the sediment and as such, were no longer PCOC. The ROD required remediation of the Tecumseh site to address the preferential pathways allowing the river to be impacted with sediments and remediation of the PCBs in river sediments.

Between 2003 and 2013, Pollution Risk Services (PRS) and others remediated preferential pathway soils and the river sediments. PRS dewatered the dredged sediment at the Tecumseh Falls and Maryland Avenue sites (Figure 1).

#### **2.2 CURRENT CONDITIONS**

Following the sediment remediation activities, the two dewatering sites have remained vacant. In accordance with the approved Sampling and Analysis Plans, SME sampled the areas where one of the geo-tubes broke releasing water outside of the dewatering pads, the wastewater treatment facilities, and the Confined Treatment Facility (CTF) or Sediment Management Facility (SMF) in 2016.

The results of this Phase II ESA demonstrated that soil at the Tecumseh Falls facility is impacted with concentrations of PCBs and PAHs; however, the impact was not the result of dewatering releases or activities by PRS. The impacted soil represents an undiscovered historical release from historical operations that occurred prior the remediation performed by PRS.

The concentrations of PAHs and PCBs at several locations at the Tecumseh Falls facility exceed the 2016 cleanup criteria or screening levels for commercial/industrial receptors. As such, impacted soil in these areas must be addressed through remediation or an engineering control before the Tecumseh facility meets the risk goals. The total cumulative direct contact risk is acceptable for commercial and industrial receptors as long as the soil impacted with PAH and PCB at concentrations above the PCSLs are addressed via remediation or engineering controls. The impacted soil also has the potential to migrate to the river or to nearby properties via two preferential pathways: surface water run-off and leaching to groundwater which then migrates to the river.

There is no residual impact from at the former CTF and SMF from sediment management activities completed by Tecumseh prior the remediation performed by PRS. Figure 2 shows the location of the impacted soil.

The results of this Phase II ESA demonstrated that soil at Maryland Avenue facility was impacted with concentrations of PAHs and lead; however, the impact is not the result of dewatering releases or activities by PRS. The impacted soil represents an undiscovered historical release from historical operations that occurred prior the remediation performed by PRS. The concentrations of PAHs and/or lead at several locations exceeded the 2016 cleanup criteria or screening levels for commercial/industrial receptors (Figure 3). As such, SME evaluated if the impacted soil in these areas need to be addressed to protect human health and the environment.

#### **3. REMEDIAL NEED EVALUATION**

#### **3.1 TECUMSEH FALLS**

Soils exceed the direct contact standards and need to be addressed. The cleanup goals established during the site investigations were as follows and were based on a 10<sup>-6</sup> risk:

- PCBs 8.66 mg/kg
- Benzo(a)anthracene 29 mg/kg
- Benzo(a)pyrene 2.9 mg/kg
- Benzo(b)fluoranthene 20 mg/kg
- Dibenz(a,h)anthracene 1.8 mg/kg
- Indeno (1,2,3-cd)pyrene 29 mg/kg.

SME used the most current Regional Screening Levels based on a 10<sup>-5</sup> risk to derive the PAH cleanup goals applicable to the potential future use of the site. These are as follows:

- Benzo(a)anthracene 210 mg/kg
- Benzo(a)pyrene 21 mg/kg
- Benzo(b)fluoranthene 210 mg/kg
- Dibenz(a,h)anthracene 21 mg/kg
- Indeno (1,2,3-cd)pyrene 210 mg/kg.

Figure 4 shows the extent of PAH impacted soils at the Tecumseh site based on the 10<sup>-5</sup> risk. Evaluation of the lateral and vertical extent of excavation required is provided in Section 4.

SME installed temporary surface water run-off controls to prevent migration of the impacted soils until we perform remedial activities. Please reference SME Serial Letter #39 (August 10, 2017) for a discussion of the controls and Serial Letter #42 (10/5/2018) for photographs of the installed silt fence.

#### **3.2 MARYLAND AVENUE**

The impacted soil is limited to four sample locations and exposure to only those soils would not be a representative site exposure to future receptors. The USEPA guidance *Calculating Upper Confidence Limit for Exposure Point Concentration at Hazardous Waste Sites* (OSWER 9285 6-10), is an update to the *Risk Assessment Guidance Document for Superfund* (RAGs). This guidance states: "Unless there is site-specific evidence to the contrary, an individual receptor is assumed to be equally exposed to media within all portions of the exposure unit over time frame of the risk assessment." RAGs stated the USEPA recommends using the average concentrations to represent "a reasonable estimate of the concentration over time." However, the OSWER update recommended using a 95% UCL as a reasonable exposure point concentration.

The concentrations of the chemicals of concern (COCs) that exceeded the 2016 screening levels at the Maryland Avenue facility are summarized below. The average COC concentrations in the soil intervals within the POC are provided demonstrating that within the POC, only the concentrations of benzo[a]pyrene are close to the screening level. However, all of the COCs will be evaluated by comparing the 95% UCL to the screening levels.

			SAMPL	E DEPTH II	NTERVAL		2018 RSL
	CHEMICALS	OF CONCERN	0-0.5	0.5-1.5	1.5-3.5	AVERAGE	OR CLEANUP CRITERIA <sup>1</sup>
	B1	Denzelelnurene	6.92	0.414	0.0406	2.5	01
	B1-1W	Benzo[a]pyrene	4.28	0.102	< 0.0032	1.46	21
		Benzo[a]pyrene	27.7	2.02	1.97	10.6	21
Commisso	H4	Benzo[b]fluoranthene	32.5	2.61	2.31	12.5	210
Samples		Lead	1,530	219	174	641	800
		Benzo[a]anthracene	29.2	4.00	0.387	11.2	210
	H4-2NW	Benzo[a]pyrene	23.2	3.73	0.455	9.1	21
		Benzo[b]fluoranthene	38.2	5.68	0.569	14.8	210
Results in m	ng/kg.						
<sup>1</sup> Using 10 <sup>-5</sup>	carcinogenic	risk and THQ of 1.0					

SME calculated the 95% UCL using the UEPA program, ProUCL. The results are summarized below and are provided in Appendix A.

CHEMICAL OF CONCERN	EXPOSURE POINT CONCENTRATION	RSL OR CLEANUP CRITERIA
Benzo[a]pyrene	5.21	21
Benzo[a]anthracene	3.48	210
Benzo[b]fluoranthene	8.04	210
Lead	175	800
Results in mg/kg.		

The exposure point concentrations are less than the screening level and exposure to site soils does not pose and unacceptable risk at a carcinogenic risk of 10<sup>-5</sup> and THQ of 1.0. Groundwater was not encountered during the investigation but there is a potential that the residual soil impact could migrate to groundwater. WDNR states in NR 720, "With the exception of naphthalene, PAH compounds are

generally only of concern for direct contact due to their relatively low migration potential. In WDNR publication RR-087, WDNR lists the concentrations of PAHs based on the Soil to Groundwater residual contaminant level (RCL). The concentrations at the Maryland Avenue site are less that these RCLs. Therefore, the soil impacted with PAHs does not appear to present a risk to groundwater. The vertical distribution of the PAHs is consistent with this conclusion.

According to the WDNR NR 720 RR Soil RCL Worksheet, the lead concentration protective of groundwater is either 13.5 or 27 mg/kg depending on the Dilution Attenuation Factor. However, the United States Geological Survey reports the state background concentrations for lead have a mean of 17.8 mg/kg and a 95% UCL of 30.1 mg/kg. The background concentrations of lead in soil compared to the RCL Worksheet implies all of the groundwater in Wisconsin is impacted with lead. However, WDNR reports in their brochure, *Lead in Drinking Water*, that "Most Wisconsin drinking water sources, either wells or lake water intakes, have little or no measurable lead." As such, the RCL defaults are extremely conservative and should be viewed as only a screening level. The following provides a weight of evidence approach as why lead at the site will not impact groundwater. This table is based on several facts affecting groundwater use in the area. Drinking Water Well Database, the closest potable water well to the Maryland Avenue site is located at 2605 Indiana Avenue, 2,400 feet to the southwest. The well is 150 feet deep and obtains groundwater from the limestone aquifer. This aquifer is separated from a shallow sand layer (4-14 feet bgs) by 61 feet of clay. The limestone aquifer is encountered at 75 feet bgs.

		VIDENCE SUMMARY FOR LEAD
FACTOR	VALUE(S)	COMMENT
Separation Distance	≈75 feet	This distance indicates there is a low probability that the impacted soil near the surface will migrate to the groundwater used for drinking water. In borings where lead was analyzed at each sampling interval, the concentration of lead decreases with depth. Based on monitoring wells at the Tecumseh site, water is found in a shallow sand layer encountered at approximately 8 feet bgs.
Representative Concentration	175 mg/kg	Lead levels above background concentration of 30.1 mg/kg were present in two locations at depths below 0.5 feet.
Partition Coefficient (Kd)	1,950 to 10,760 L/kg	Lead has a very high Kd indicating that it does not have the tendency to leach to groundwater.
Solubility	Insoluble to soluble	Literature indicates all but two forms of lead (salts, carbonates, sulphates, etc.) are insoluble in water at ambient temperatures. Only lead acetate and lead nitrate are soluble. Lead acetate is highly soluble but does not occur in nature as it is manufactured with lead and acetic acid. Lead nitrate is also not found in nature as is the byproduct of mixing lead and nitric acid.
Secondary Features	None	There are no fractures or deep utilities that would aid migration of leachate to groundwater.
Other	Migration Potential	According to the Sheboygan County Soil Survey, soils in this area have a pH above 7 and a cation exchange capacity of more than 10 me/100 grams. These soil characteristics increase retardation factor and reduce leaching.

The residual impact poses no threat to receptors or groundwater. As such, SME and PRS recommended that no further action is required at the Maryland Avenue facility.

#### 4. TECUMSEH REMEDIAL EXTENT EVALUATION

The Phase II and delineation investigations have defined the extent of PAH and PCB impact at the site. Figures 4 through 6 depicts the extent of impact above the direct contact cleanup levels. The PAH impacted soil extends to a depth of no more than 4 feet below ground surface (bgs). Approximately 244 cubic feet of soil is impacted with PAHs exceeding acceptable risk levels (Figure 4).

The extent of PCB impact is dependent on using the Wisconsin direct contact point of compliance of 0 to 4 feet bgs<sup>1</sup> as a cleanup or capping requirement or using all PCB impacted soils as the cleanup or capping requirement. Figures 5 and 6 show the extent of impact depending on the depth of impact that has to be addressed. Depending on the depth of soil to be remediated to address PCBs, there is 5,448 to 17,195 cubic yards of soil. The 95% UCL for the PCBs in soil is 1,124 mg/kg. In the event of off-site disposal, all of the soil has to be disposed in a TSCA waste landfill.

During the supplemental delineation assessment of the PCB impacted soils at the Tecumseh site, SME collected samples for Synthetic Precipitation Leaching Procedure (SPLP) analysis to assess the propensity of PCB to leach from the soil. This information will allow a determination of the concentrations that are protective of the leaching to groundwater pathway. Empirical evidence from the 2016 and 2017 investigations of this site indicates PCB concentrations as high as 15,000 mg/kg may not significantly leach to groundwater. At sample location S15-1W, the PCB concentration is 1,030 mg/kg from 0-0.5 feet bgs reducing to 0.938 mg/kg at 1.5 to 3.5 feet bgs. The SPLP test provided evidence that PCBs would leach to groundwater. However, evidence that PCBs will not leach to groundwater is that groundwater results from the two monitoring wells down-gradient of the most impacted area, MW10 and MW12, have seen decreases in PCB concentrations of 45% and 65% respectively. In addition, BB&L installed a shallow and deep well in the area, MW7S and MW7D, and sampled the wells for total and dissolved PCBs. No PCBs were detected in the groundwater. A groundwater interceptor trench is present in the event the concentrations in groundwater increase. Use of the trench has never been necessary. Based on the foregoing, leaching to groundwater is not a pathway to consider when determining the vertical extent of impact that must be removed.

Based on the results, the soil impact will have to be addressed to protect the public from direct contact with soil. During the remediation, steps should be taken to reduce the chance that PCBs may leach to groundwater.

#### **5. ANALYSIS OF REMEDIAL ALTERNATIVES**

#### **5.1 EVALUATION CRITERIA**

An analysis of remedial alternatives was completed based on three criteria: Threshold, Balancing, and Modifying. The criteria provided decision makers adequate information to allow the selection of an appropriate remedy of the Property. Additional information on the criteria used to select the most appropriate remedial method are described below.

- The Threshold Criteria include:
  - o Protection of Human Health and the Environment
  - Compliance with Applicable or Relevant and Appropriate Requirements (ARARs)

<sup>&</sup>lt;sup>1</sup> WDNR Publication RR-968, RR-709, RR-528, and WDNR Form 4400-202.

- The Balancing Criteria include:
  - Long and Short-Term Effectiveness
  - Reduction in Toxicity or Mobility
  - o Implementability
  - o Cost
- The Modifying Criteria include:
  - o Community Support
  - o Responsible Party Support
  - o State Support

In preparation of this RAP, we developed Site-Specific cleanup levels (Section 3.1) based on the Property's future use and estimated the extent of impact requiring remediation. The ability of remedial alternatives to meet these standards in the short and long-term will help meet one of the Threshold Criteria. As part of this criteria, we evaluated the ARARs to determine if there are other local, state, or federal criteria that must be met as well as those applicable to the remedial action such as storm-water control, fugitive or particulate emissions control, and prohibition of nuisances.

We also evaluated the range of possible costs for each remedial alternative, the effectiveness of each alternative, and the ability to meet the Site-specific standards. In addition, we evaluated the ability of the alternatives to gain state and community (parents of students) support through outreach efforts.

#### **5.2 POTENTIAL REMEDIAL ALTERNATIVES**

We reviewed the following documents for a list of potential remedial alternatives.

- USEPA, Technology Alternatives for the Remediation of PCB Contaminated Soils and Sediments, EPA/600/S-13/079.
- Los Alamos National Laboratory, A Compendium of Cost Data for Environmental Remediation Technologies, August 1996.
- USEPA, The Feasibility Study: Detailed Analysis of Remedial Action Alternatives, March 1990.
- Goldstein, Mike and Ritterling, Jon, *A Practical Guide to Estimating Cleanup Costs*, USEPA Papers, Paper 30, January 2001.
- USEPA, Guidance for Conducting Treatability Studies Under CERCLA, October 1992.
- USEPA, Table 3-2: Treatment Technologies Screening Matrix.
- Dadrasnia, Arezo, Shahsavari, N., and Emenike, C.U., *Remediation of Contaminated Sites*, 2013.
- Mouvet, Christophe and Colombano, Stefan, *Remediation Technologies for PAH Contaminated Soils*, October 2012.

These documents provided the following remedial alternatives that may be effective for PCBs:

- Soil Removal and Off-site Disposal or Incineration
- In Situ Treatment
  - No Action/Natural Attenuation
  - Biological Treatment
    - Bioremediation

- Phytoremediation
- Engineering Control (Capping)
- Vitrification
- Solvent Extraction
- Solidification
- Nano-Valent Iron Reductive Dechlorination
- Sorbent Polymer Extraction and Remediation System (SPEARS)
- Ex Situ Treatment
  - Chemical Treatment
  - > Vitrification
  - Bioremediation

#### **5.3 SCREENING LEVEL EVALUATION OF REMEDIAL ALTERNATIVES**

Of the potential remedial alternatives listed in Section 5.2, SME performed a screening level evaluation of the remedial alternatives with the exception of "No Action" (Table 1). The screening evaluation was based on each of the three main criteria discussed in Section 5.1: overall protection of human health, relative cost, and community support. The following provides a summary of this evaluation of the top alternatives, based on the screening evaluation.

REMEDIAL ALTERNATIVE	SCREENING EVALUATION SCORE	RELATIVE COST	COMMENT
1. Soil Removal	62.5	>\$10,00,000	Relatively fast to implement
2. Engineering Control	62.5	<\$500,000	Fastest to implement and is consistent with current engineering control
3. In-Situ Bioremediation	55	<\$1,000,000	A lengthy process

#### **5.4 DETAILED EVALUATION OF APPLICABLE REMEDIAL ALTERNATIVES**

Of the three remedial alternatives identified by SME to be most effective, we performed a detailed evaluation of the alternatives based on all of the criteria using a scoring spreadsheet developed based on the guidance document, *Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA*. Appendix B provides the results of this evaluation. A summary of the scores for each remedial alternative evaluated is provided in the following table.

REMEDIAL ALTERNATIVE	DETAILED ANALYSIS SCORE	RELATIVE COST	COMMENT
1. Soil Removal	81	>\$10,00,000	Read on sears, select
2. Engineering Control	81	<\$500,000	Based on score, select Engineering Control
3. In-Situ Bioremediation	80	<\$1,000,000	Engineering Control

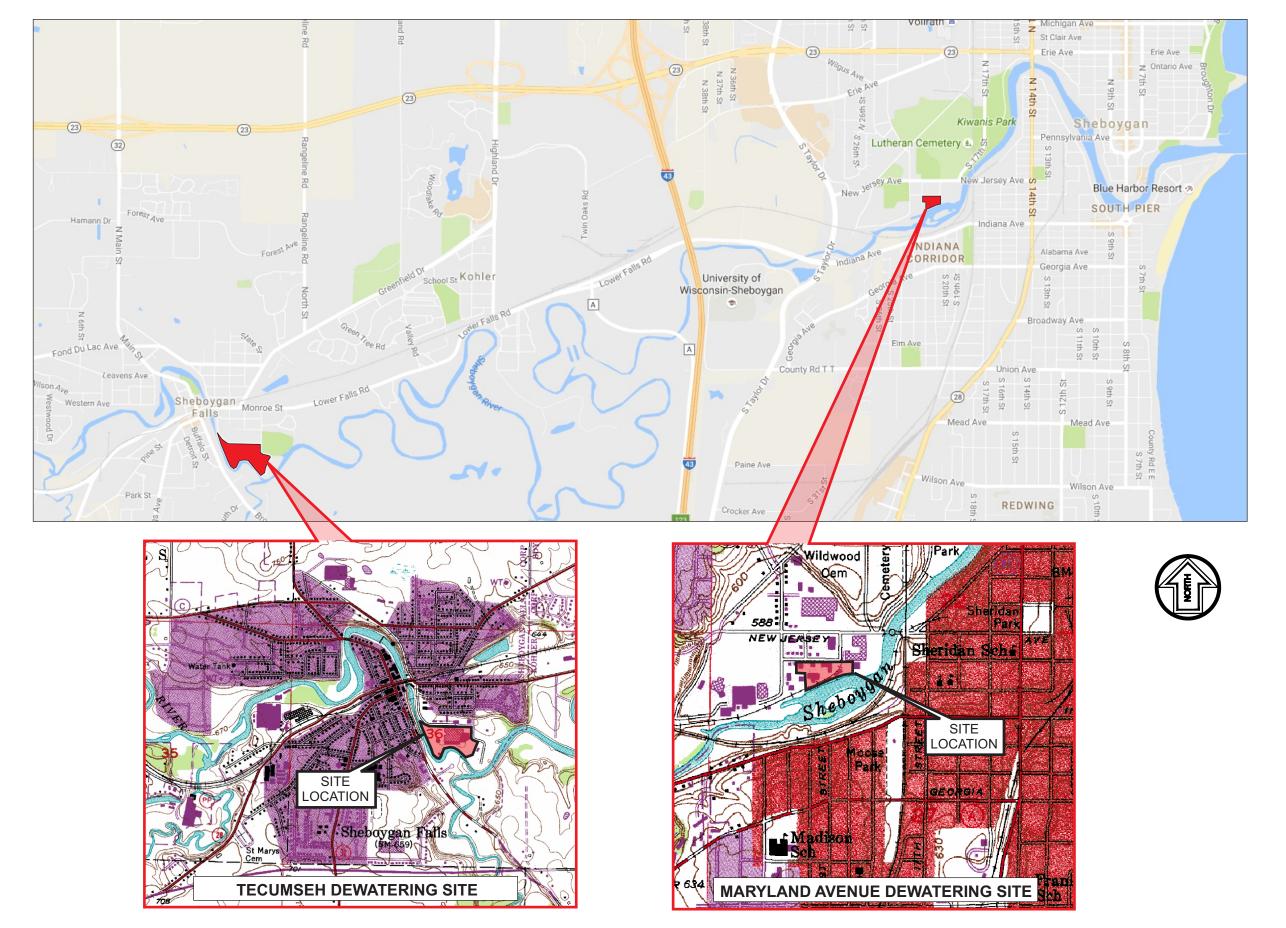

Both the screening evaluation and the detailed analysis scoring demonstrate the Alternative 2 should be the selected remedy. Capping is consistent with WDNR philosophy as discussed in Section 3.2 of RR-528 that "A soil performance standard implemented to protect human health from direct contact would typically involve capping the contaminated soil".

#### **6. CONCLUSIONS**

The soil at the Tecumseh Falls facility should be capped to protect the public and groundwater. The soil at the Maryland Avenue facility does not pose a risk to the public.

#### **APPENDIX B** REMEDIAL ALTERNATIVES SCORING SHEET

#### DETAILED ANALYSIS SCORING SHEET ALTERNATIVE 1 – SOIL REMOVAL

#### **SUMMARY OF SCORING**

#### ALTERNATIVE 1

AREA	SCORE
Compliance with ARARs, Criteria 7 Guidelines	10
Protection of Human Health and the Environment	20
Short-term Effectiveness	9
Long-term Effectiveness and Performance	12
Reduction of Toxicity, Mobility, Volume	17
Implementability	13
Cost (0-10, "10" is most economical)	0
TOTAL	81

Analysis Factor	<b>Basis for Evaluation During Detailed Analysis</b>	Applic	ability		
<b>COMPLIANCE WITH ARARs, STA</b>	NDARDS, CRITERIA, AND GUIDELINES	YES	NO	So	core
1. Chemical-specific ARARs	i) Meets chemical specific ARARs such as groundwater standards.	X 4	0	=	4
2. Action-specific ARARs	ii) Meets ARARs such as technology standards for incineration or landfill.	X 3	0	=	3
3. Location-specific ARARs	iii) Meets location-specific ARARs such as Freshwater Wetlands Act.	X 3	0	=	3
Note: ARARs - Applicable or Relevant an	d Appropriate Requirements	TOTAL (maxim	um = 10)	=	10
PROTECTION OF HUMAN HEALT	TH AND THE ENVIRONMENT	YES	NO	Sc	core
1. Use of Site after remediation.	i) Unrestricted use of land and water. (If yes, go to end of the Table)	X 20	0	=	20
	ii) Future redevelopment of land and water constrained	0	10		0
		Sub-Total (maxi	mum = 20)	=	20
2. Human health and environment	i) Is the exposure to contaminants via route acceptable?	3	0	=	0
exposure after the remediation	ii) Is the exposure to contaminants via ground/surface water acceptable?	4	0	=	0
	iii) Is the exposure to contaminants via sediments/soils acceptable?	3	0	=	0
		Sub-Total (maxi	mum = 10)	=	0
3. Magnitude of residual public	i) Health risk ≤ 1 in 1,000,000	5	0	=	0
health risks after remediation.	ii) Health risk ≤ 1 in 100,000	2	0	=	0
		Sub-Total (max	ximum = 5)	=	0
4. Magnitude of residual environ-	i) Less than acceptable	0 5	0	=	0
mental risks after remediation.	ii) Slightly greater than acceptable	3	0	=	0
	iii) Significant risk still exists	0	0	=	0
		Sub-Total (max	<b>ximum</b> = 5)	=	0
		TOTAL (maxim	um = 40)	=	20
SHORT-TERM EFFECTIVENESS		YES	NO	So	core
1. Protection of community during	i) Are there significant short-term risks to community that must be addressed? (if no, go	to 2) 0	X 4	=	4
remedial actions.	ii) Can the risk be easily controlled?	1	0	=	0
	iii) Does the mitigative effort to control risk impact community life-style?	0	X 2	=	0
		Sub-Total (max	(imum = 4)	=	4
2. Environmental Impacts	i) Are there short-term risks to environment that must be addressed (if no, go to 3)	0	X 4	=	4
-	ii) Are there significant mitigative measures reliable to minimize potential impacts	3	0	=	0
		Sub-Total (max	(imum = 4)	=	4
3. Time to implement the remedy	i) Is the required time to implement the remedy $\leq 2$ yrs?	X 1	0	=	1
	ii) Required duration of the mitigative effort to control short-term risk $\leq 2$ yrs?	1	X 0	=	0
		Sub-Total (max	ximum = 2)	=	1
		TOTAL (maxim	$\mathbf{um} = 10$	=	9
		(			

Analysis Factor	<b>Basis for Evaluatio</b>	n During Detailed Analys	sis	Applicability					
LONG-TERM EFFECTIVENESS AN	D PERFORMANCE			YES NO					
1. On-site or off-site treatment or	i) On-site treatment Note: treatment is defined as destruction, 3							0	
land disposal.	ii) Off-site treatmentseparation/treatment, or solidification/iii) On-site or Off-site land disposalchemical fixation.					X 0	=	0
