

# WISCONSIN TROUT STREAMS

## Our Mission:

To protect and enhance our natural resources:  
our air, land and water;  
our wildlife, fish and forests  
and the ecosystems that surround them.

To provide a clean, sustainable environment  
and a full range of outdoor opportunities.

To insure the right of all Wisconsin citizens  
to use and enjoy these resources  
in their work and leisure.

To work with people  
so that we understand their views  
and can carry out their will.

And in this partnership with our citizens,  
consider the future  
and those who will follow us.

# Wisconsin Trout Streams

## Introduction

This comprehensive list of trout streams has been updated for 2002 using the latest trout survey information. Since the last publication of the “Wisconsin Trout Streams” in 1980, numerous changes have occurred. The total number of trout streams has increased by 254, and the miles have increased by 809. The miles of class 1 trout streams have increased by 600 miles, the miles of class 2 have increased by 401 miles, and the miles of class 3 have decreased by 192 miles. Most of the increases have occurred in the southwestern and west central counties of Iowa, Richland, Vernon, Pierce, Dunn, and Trempealeau. The reasons for these changes are numerous, including changing land use patterns, land conservation measures, habitat restoration and protection, and wild trout stocking.

## Stream Classification

All streams added since the 1980 edition satisfy the legal requirements for trout stream classification in Administrative Code, NR 1.02(7). We will continue to update this list as more classifications are completed. This classification is for fisheries management purposes and does not satisfy the legal requirements for classifying cold water streams for water quality protection using discharge permits.

Wisconsin trout streams are placed into three classes for fish management purposes:

**Class 1.** These are high quality trout waters, have sufficient natural reproduction to sustain populations of wild trout at or near carry capacity. Consequently, streams in this category require no stocking of hatchery trout. These streams or stream sections are often small and may contain small or slow-growing trout, especially in the headwaters. There are 4,136 miles of Class 1 streams and they comprise 40% of Wisconsin’s total stream mileage.

**Class 2.** Streams in this classification may have some natural reproduction, but not enough to utilize available food and space. Therefore, stocking is required to maintain a desirable sport fishery. These streams have good survival and carryover of adult trout, often producing some fish larger than average size. There are 4,644 miles of class 2 streams. They comprise 45 % of the total trout stream mileage.

**Class 3.** These waters are marginal trout habitat with no natural reproduction occurring. They require annual stocking of trout to provide trout fishing. Generally, there is no carryover of trout from one year to the next. There are 1,591 miles of class 3 streams. Class 3 streams comprise 15% of the total trout stream mileage.

## Maps

This edition does not contain maps of Wisconsin trout streams. Maps of trout streams are currently being constructed using GIS technology (Geographical Information System) and should be available soon.

## Trout Species

**Brook Trout** (*Salvelinus fontinalis*). Brook trout are the only stream trout species native to Wisconsin. They are the most delicate and require cold, well-oxygenated, clean water. They are not great wanderers, seldom traveling more than a few miles from their spawning sites. Brook trout are usually found in the forested northern half of the state in headwaters of streams and spring feeder streams, although brook trout are making a comeback in many southwestern and west central streams. Because they are easy to catch and usually reside in small streams, they seldom grow as large or live as long as brown trout or rainbow trout. Most brook trout taken by anglers are between 6 to 9 inches long. The largest brook trout caught on inland waters in Wisconsin weighed 9 pounds and 15 ounces. It was caught on the Prairie River in Lincoln County in 1944.

Successful natural reproduction is dependent on upwelling, well-oxygenated groundwater. Stream flow through and over gravel spawning nests (redds) must be low in suspended silt and sand which can smother developing eggs or fry. Spawning occurs in the fall, usually between mid-October and mid-November.

**Brown Trout** (*Salmo trutta*). Brown trout were introduced into the state in 1887 and adapted well to Wisconsin streams. Their hardy nature, aggressive behavior, greater wariness and long life span account for their wider distribution. Brown trout have also replaced less tolerant brook trout in streams that have become too warm and organically polluted. Brown trout predominate in the large, fertile streams in southern and east central Wisconsin and in the Driftless Area.

Natural reproduction depends on adequate stream flow of suitable temperature passing horizontally through gravel spawning redds or vertical upwellings of groundwater at spawning sites. Brown trout also spawn in the fall but usually a little later than brook trout. Since large trout require more space, the largest specimens are usually found in larger streams or lakes.

Experienced trout anglers know that brown trout are the wariest species of all. Even hard-fished streams usually contain some brown trout that survive to much larger sizes than brook trout. Hatchery-reared browns are stocked in some Class II and most Class III streams. Stocking of fingerlings (trout 3 to 5 inches long) occurs in early fall while stocking of legal-sized fish occurs in spring prior to opening day of fishing. Brown trout are avid insect feeders at all sizes, but those over 12 inches tend to shift more to a diet of minnows, snails, and crayfish. Most browns harvested are eight inches and larger. The Wisconsin record brown trout taken by hook and line in inland waters weighed 18 pounds and 6 ounces and was 34.3 inches long. It was caught in Lake Geneva, Walworth County in 1984.

**Rainbow Trout** (*Oncorhynchus mykiss*). Rainbow trout were brought into the state from the Pacific coast where they are native. They grow rapidly, are easily caught, and are very sporting when hooked. Naturally reproducing populations of rainbow trout occur in some northern streams and a few streams in central Wisconsin. However, most sport fisheries for rainbow trout are dependent on annual stocking of fingerling trout in late summer or legal-sized yearling trout in the spring. This species prefers faster water habitats than do brook or brown trout of the same size. Spawning occurs in the spring, usually at the head of gravel riffles near undercut stream banks. There is currently no inland angling record for rainbow trout.

## **Habitat Losses**

Degradation of trout habitat is one of our most serious management problems. Serious loss of habitat is caused by siltation from erosion, decreased groundwater flow from irrigation, drained wetlands and poor watershed management. High oxygen demand from organic pollution, channelization, cattle grazing, and increased temperatures from both man-made and beaver-constructed dams and impoundments are other common causes of trout habitat deterioration.

Beaver can seriously threaten trout habitat. Small or low gradient trout streams can be easily dammed, causing changes in water temperature, habitat, and access to spawning areas. Beaver ponds change the habitat upstream by killing trees, warming the water in summer and cooling it in winter, and creating a shallow dishpan shape with no undercut banks. The beavers leave when the food supply is gone, and the dam eventually washes out. A "beaver meadow" develops that is free of woody vegetation with only grasses and sedges present. In a low gradient stream, years may pass before the area regains its former trout productivity.

Trout habitat is also lost where cattle are allowed to graze uncontrolled along the stream. Cows break down undercut stream banks that are favorite hiding places for trout. Streamside vegetation is unable to survive intensive grazing and stream banks become subject to erosion. Streams eventually lose their capacity to hold trout. Rotational grazing has shown promise by controlling woody vegetation and not beating down the banks.

Excessive stream siltation also results when good soil conservation practices are not practiced or when new roads are built without adequate precautions for protecting disturbed soil from erosion.

There are a number of other causes of trout habitat losses. Some occur naturally but most of them are a result of man's activities. State laws protect trout streams from pollution and other harmful effects such as stream channelization or alteration, dam construction and excessive irrigation.

## **Trout Stamp**

Fortunately, damaged trout streams can be restored. Through research and experimentation, we have developed techniques that effectively restore damaged habitat. Streams in their natural state can also be improved to greatly increase their capacity for producing trout.

Prior to 1977, little habitat development could be done because funds were not available. In 1977, the Legislature provided the Department of Natural Resources with the authority to sell trout stamps solely for the purpose of trout habitat improvement. This law became effective January 1, 1978. Since 1978 about 25 miles of trout streams per year have been restored with the aid of trout stamp revenue. Trout stamp sales have varied from a high of 195,000 in 1981, to a low of 108,000 during the drought of 1990. Currently, about 140,000 are sold which generates about \$1.2 million for habitat restoration.

Restoration activities include fencing banks to keep cattle out, protecting banks with rock and vegetation, providing shelter in the stream and along stream banks, and brushing stream banks to encourage grassy vegetation that stabilizes undercut banks.

Studies have shown that pools and permanent cover are important ingredients for trout welfare. Much of our efforts are directed towards providing these ingredients where they are needed. It is not unusual to find trout numbers increasing two or three times their previous levels as a result of stream habitat improvement.

## **Stocking**

Some of our trout streams have an abundance of food and excellent water quality but they lack spawning areas. To date, we had limited success in providing artificial spawning areas. Hatchery trout are stocked in waters lacking sufficient native trout to meet the demands of anglers who enjoy fishing trout streams. In 2002, the nine Wisconsin State hatcheries and two cooperative rearing operations will stock about 1.9 million trout in inland waters. All stocking costs, including warmwater, total \$5.7 million, or about 22% of our total fisheries management budget.

Legal-sized trout are stocked just before or during the early part of the trout season. This is done to ensure a good return of stocked fish because mortality of catchable stocked trout is quite high. Only small numbers of these fish will carry over into the next season. About 40% of the trout stocked are yearlings.

Where conditions for survival are good, fingerling trout are stocked in late summer or early fall. These trout range between three to six inches in length. This procedure reduces trout rearing costs and provides anglers with fish that have acclimated to the stream and results in better use of food resources in the stream. About 60% of the trout stocked are fingerlings. Trout spawned from “wild” parents have been stocked in better class 2 streams and have shown better survival than “domestic” hatchery trout. Because of the positive results seen from stocking wild trout, they now comprise about a third of the total trout stocked in inland waters.

## **Regulations**

Since 1990, a category system has been used to manage for a variety of fishing opportunities that anglers desire. Size and bag limits vary by category to match the productivity of the stream, the fishing pressure, and the desires of anglers.

Hatchery reared trout are usually easier to catch than native trout. This is especially true of brook and rainbow trout. Streams stocked with legal trout tend to be fished hard and restrictive regulations are required to ensure an equitable distribution of fish among anglers.

Many streams are now being managed to permit a limited harvest or on a catch-and-release basis. Much more recreation can be provided by such regulations. This type of management works well on streams subject to heavy fishing pressure.

## **Land Acquisition**

Although not a highly visible program, the purchase and leasing of lands along trout streams is probably our most important management activity. This land control program protects streams from harmful land management practices. It also allows trout fishermen an opportunity to fish without fear of trespass.

## **Summary**

Trout stream management is everyone's responsibility. As an angler, you are in a good position to help in preserving this critical resource. Picking up litter will do much to preserve the beauty of our trout streams. Reporting fish kills and evidence of pollution or habitat destruction in a timely fashion is an important activity which anglers can do to help preserve our great trout fishing for the future.

## **Trout Codes**

The following codes are used in the trout species columns of this report:

n = naturally reproducing species

x = stocked species

a = anadromous (migrating from a lake to a stream to spawn) species

It is important to the Wisconsin Department of Natural Resources that you find this report useful. To better meet this goal, direct your suggestions for improving this report to:
